REPORT 058-ATD.02.01  
MODEL Gemini B**ABSTRACT**

Testing was conducted on three, 9 percent scale Gemini models and a 5.8-inch diameter hemisphere cylinder to obtain qualitative and semi-quantitative information on the local heat transfer rate induced on the Gemini afterbody by the module/adapter interconnect fairing. These models were cast using RTV 60 silicone rubber. A 0.3-inch minimum thickness of rubber was maintained over an aluminum core.

The Gemini models were tested at 160°, 165°, and 170° angle of attack. The hemisphere cylinder was tested at 0° angle of attack. Testing was conducted at Mach 8 at Reynolds numbers per foot of 3.8, 3.5, 3.0, 2.0, and  $1.0 \times 10^6$ . Prior to each run, models were coated with Detecto-Temp paint. Color motion pictures were made during the test to obtain color change data, and still photographs of the models were taken after each run. Forty-seven runs were completed during Series I tests and 27 runs during Series II tests. The motion pictures and still photographs have been forwarded to Department 242 for analysis.

These tests were performed in Tunnel B of the von Karman Gas Dynamics Facility, Arnold Engineering Development Center on 10 August 1967 (Series I) and 4 November 1967 (Series II).

This report completes work on TR 058-ATD.02.01.

REPORT 053-ATD.02.01  
MODEL Gemini B

## 1. INTRODUCTION

Testing was conducted on 9 percent scale Gemini rubber models and a 5.8-inch-diameter hemisphere cylinder to obtain qualitative and semi-quantitative information on the local heat transfer rate induced on the Gemini afterbody by the module/adapter interconnect fairing. The test was set up to obtain comparative information between the NASA GT2 fairing, the Gemini B low-profile fairing, and the model with no fairing. The analysis was to be made with theoretical heating rates on a reference hemisphere cylinder.

These tests were performed on models painted with Detecto-Temp paint in Tunnel B of the von Karman Dynamics Facility, Arnold Engineering Development Center (AEDC), on 10 August 1967 (Series I) and 4 November 1967 (Series II).

## 2. MODEL DESCRIPTION

Three 9 percent scale Gemini models were fabricated for the test program. Female plaster molds were made for each configuration of the Gemini to be tested. An existing 9 percent scale Gemini model was used as the master for the plaster molds. Inner cores were machined from 2024 T-3 aluminum and provided a gap of 0.3-inch minimum between the core and the mold. RTV 60 silicone rubber, which was exposed to a vacuum to remove air bubbles, was injected into the gap and allowed to cure at room temperature for 48 hours. The model was then removed from the mold and hand finished.

The Gemini configurations cast were:

- (1) Gemini with the NASA fairing;
- (2) Gemini with the Gemini B fairing; and
- (3) Gemini without a fairing.

A similar casting technique was employed to cast a 5.8-inch diameter hemisphere cylinder using a female fiberglass mold furnished by AEDC. The

REPORT 058-AED.02.01  
MODEL Gemini B

hemisphere cylinder was used as the calibration body during the test program. Sketches of the models are shown on pages 4 and 5.

All models were cast from the same batch of silicone rubber. The nominal thermal conductivity of the RTV 60 is  $0.18 \text{ Btu-ft/hr-ft}^2\text{R}$ .

### 3. TEST SETUP

The models were installed in Tunnel B at AEDC using the hardware shown in the sketches on pages 6 and 7. Roll locking devices were not provided on the models during Series I tests and the Gemini model with the NASA fairing was inadvertently rolled an additional  $+7^\circ$  from its intended test position. A roll locking device was installed on the models for Series II tests.

Two DBM-5A Millikan motion picture cameras were used to record the test on color film. One camera was located in the top forward window, the other in the side forward window. A bank of four iodized quartz lamps was located in the upper aft window. A similar bank of lamps was located in the side aft window to provide tunnel lighting. The cameras were focused on the afterbody of the Gemini model with a bore sight tool. Camera location and lens setting remained in the same position for the entire test program.

### 4. TEST PROCEDURE

Grid lines were drawn on the clean Gemini model and the hemisphere cylinder to provide a reference for film interpretation. Film sequences were made of the Gemini model at  $160^\circ$ ,  $165^\circ$ , and  $170^\circ$  angle of attack, and of the hemisphere cylinder at  $0^\circ$  angle of attack.

The models were painted with Detecto-Temp paint (915-0979) and allowed to dry. Next, the models were installed on the sting support system in the model installation room beneath the tunnel test section.

REVISED \_\_\_\_\_

MODEL Gemini B

When tunnel flow conditions were established, the motion picture cameras were started and the model was injected into the tunnel. An event marker was placed on the film when the model reached tunnel centerline. Visual observation of the model during the test for color changes and patterns was used as a guideline for the length of time the model remained in the tunnel.

After each test, the model was removed from the sting support system and a still color photograph was taken.

Testing was conducted on the four models at angles of attack of 160°, 165°, and 170° for the Gemini models and at 0° for the hemisphere cylinder. All tests were conducted at Mach 8 at Reynolds numbers per foot of 3.5, 3.0, 2.0, and  $1.0 \times 10^6$  for Series I tests and at Reynolds numbers per foot of 3.8, 3.0, and  $2.0 \times 10^6$  for Series II tests.

### 5. TEST RESULTS

Test results are:

- (1) color movies;
- (2) color negatives of still photographs; and
- (3) a run schedule consisting of configuration, test conditions, and movie identification.

The color movies and still photographs have been forwarded to Department 242 for analysis.

The run schedule is presented in tables on page 8 through 10.
